

This project analyzes a mock marketing campaign dataset to identify which channels generate the strongest return on investment (ROI). The goal is to provide data-driven recommendations on how the company could allocate marketing budget more effectively. The analysis uses Python to explore campaign cost, revenue generated, ROI, and the relationship between spending and revenue across marketing channels. This is an early Python portfolio project. I used AI-assisted debugging, documentation, and publicly available notebook examples to support the development process. All analysis, interpretation, and business recommendations were reviewed and completed by me.

Mock Marketing Report

Marketing Performance

Overview

This project analyzes a mock marketing campaign dataset to identify which channels generate the strongest return on investment (ROI). The goal is to provide data-driven recommendations on how the company could allocate marketing budget more effectively. The analysis uses Python to explore campaign cost, revenue generated, ROI, and the relationship between spending and revenue across marketing channels. This is an early Python portfolio project. I used AI-assisted debugging, documentation, and publicly available notebook examples to support the development process. All analysis, interpretation, and business recommendations were reviewed and completed by me.

Report Goal

Using the 70-20-10 method I will recommend the best distribution of our funds between our marketing channels for the next quarter. While also discussing important indications for us to watch as we move forward.

Top 5 Most Effective Marketing Channels

Median ROI from each marketing channel helps us distinguish which channel consistently gives us the best returns. While also ignoring outliers when marketing channels perform in an inconsistent manner.

● Median ROI

Forward Facing Plan (70-20-10)

70-20-10 channel theory recommends allocating marketing spending into three categories. 70% for Proven channels, 20% for Emerging channels, and 10% for experimental channels.

By keeping 5-6 main channels in rotation that meet this criteria I believe that we are actively taking the right steps to allocate our funds in an effective way.

Next Steps and Notes

Continual monitoring of ROI quarterly and recategorizing our channels is recommended to see continual growth. Channels should also always be screened for spread using ML trend-lines and r^2 values to ensure that we do not have volatile channels that offer inconsistent returns.
